

Turn scattered bug and player data into a **decision-ready** knowledge base

The Problem

Your quality knowledge — bug reports, crash logs, player complaints, patch histories, QA checklists — is scattered across trackers, community channels, and build pipelines, and locked in your senior QA leads' heads. Linking a live complaint spike to the build change that caused it takes days; release judgment depends on who's in the room.

What Neuron Does

It links every record into one ontology-structured database anchored to each build version and bug ID, so your team gets instant answers to "did this regression pattern appear in past builds?" and "which platforms and player segments does this hit?" — without changing how you work today.

What you can do with the centralized database

01

Detect regression signs before release

Flag builds whose test results and crash patterns trend toward past live incidents, so risks are caught in certification — not in launch-day reviews.

02

Check exposure across platforms and versions

When one platform shows a defect, instantly see occurrence and crash rates across other platforms, regions, and client versions and judge the full player impact.

03

Verify patches actually worked

Track whether the same bug class or complaint spike recurred across similar features and builds after each hotfix — evidence you can show players and leadership.

04

Make live-ops decisions with full context

Surface similar past incidents, rollback outcomes, and player-sentiment history at decision time, so nothing gets missed under launch pressure.

"When a complaint spike hit at launch, tracing it to a build change took all night. Now the connection — and how we handled it last time — is on screen in minutes."

QA Director - Mobile game studio

See it with your own data

We start with a focused PoC using your existing QA data — bug exports, crash reports, player feedback, as they are. No system migration, no process change required.
