

Turn scattered site records into a **decision-ready** knowledge base

The Problem

Your project knowledge — inspection records, defect punch lists, RFIs, site photos, subcontractor reports, handover documents — is scattered across project folders, chat apps, and paper binders, and locked in your veteran site managers' heads. Finding whether a defect pattern appeared on past projects takes days; quality depends on who runs the site.

What Neuron Does

It links every record into one ontology-structured database anchored to each project, building, and unit ID, so your team gets instant answers to "where else did this detail fail before?" and "which subcontractor's work shows this pattern?" — without changing how you work today.

What you can do with the centralized database

01

Detect defect patterns before handover

Flag units and details trending toward past post-handover claim patterns, so rework happens during construction — not under warranty.

02

Check risk across buildings and projects

When one unit shows a defect, instantly see every unit sharing the same detail, material lot, or subcontractor crew and judge the full exposure.

03

Verify rework actually fixed the root cause

Track whether the same defect recurred across projects and crews after each corrective measure — evidence you can show owners and management.

04

Make handover decisions with full context

Surface similar past defects and owner-specific checkpoints at inspection time, so nothing gets missed on delivery day.

"A leak pattern we fought on a past project reappeared on a new site — and nobody remembered until it was too late. That's exactly the connection we now catch in minutes."

Construction Quality Manager - General contractor

See it with your own data

We start with a focused PoC using your existing site records — punch lists, inspection sheets, photos, as they are. No system migration, no process change required.
