

Turn scattered asset history into a **decision-ready** knowledge base

The Problem

Your asset knowledge — inspection reports, maintenance logs, incident records, sensor anomalies, vendor reports — is scattered across CMMS exports, PDFs, and field notebooks, and locked in your veteran technicians' heads. Finding how a similar failure was handled takes hours; outage response depends on who's on shift.

What Neuron Does

It links every record into one ontology-structured database anchored to each asset ID, so your team gets instant answers to "what preceded this failure pattern before?" and "which other assets share this condition?" — without changing how you work today.

What you can do with the centralized database

01

Detect failure signs before outages

Flag assets whose inspection findings and anomaly history trend toward past-failure patterns, so interventions happen on schedule — not after the trip.

02

Check risk across the asset fleet

When one transformer, turbine, or line section fails, instantly see every asset of the same type, age, and service condition and judge the full exposure.

03

Verify maintenance actually worked

Track whether the same failure mode recurred across similar assets after each overhaul or design change — evidence you can show management and regulators.

04

Make repair-or-replace decisions with full context

Surface each asset's complete history and similar past cases at judgment time, so capital decisions rest on evidence, not memory.

"When a veteran retired, thirty years of asset knowledge nearly walked out the door. Now his inspection judgments are searchable by every engineer on the team."

Maintenance Planning Manager - Power utility

See it with your own data

We start with a focused PoC using your existing asset files — inspection reports, work orders, incident logs, as they are. No system migration, no process change required.
