

Turn scattered fault history into a **decision-ready** knowledge base

The Problem

Your network knowledge — fault tickets, site maintenance logs, outage postmortems, customer complaints, vendor reports — is scattered across OSS tools, spreadsheets, and field notes, and locked in your senior NOC engineers' heads. Linking a recurring fault to its site history takes hours; restoration speed depends on who's on shift.

What Neuron Does

It links every record into one ontology-structured database anchored to each site and network element ID, so your team gets instant answers to "what preceded this fault pattern before?" and "which sites share this configuration and risk?" — without changing how you work today.

What you can do with the centralized database

01

Detect degradation signs before outages

Flag sites whose alarm and maintenance history trends toward past-outage patterns, so preventive dispatch happens before customers notice.

02

Check exposure across the network

When one element fails, instantly see every site sharing the same hardware batch, firmware, or environment and judge the full service impact.

03

Verify fixes actually cut recurrence

Track whether the same fault class recurred across similar sites after each fix or vendor swap — evidence for vendor negotiations and capex plans.

04

Dispatch with full site context

Surface each site's complete history and similar past faults at ticket time, so field crews arrive with the right part and the right hypothesis.

"A tower fault that stumped the night shift matched a case from two years ago at a sister site — same firmware, same fix. That answer used to depend on one engineer's memory."

NOC Manager - Regional telecom operator

See it with your own data

We start with a focused PoC using your existing network records — fault tickets, maintenance logs, postmortems, as they are. No system migration, no process change required.
